ABSTRACT

Butterflies play vital role in the ecosystem, there is co-evolutionary relationship between butterflies and plants, their lives are interlinked. Butterflies are also called flying flower, whenever goes displaying its beauty. These insects enhance the aesthetic value of the environments by their exquisite wing colors. Butterflies are the wild indicators of the ecosystem; these insects tell us everything about the healthier ecosystem. These are effective pollinators, butterflies visit the flower to eat nectar, tiny scales on their bodies brush against the anthers and pollen sticks to these scales, then butterfly visits the next flower, the pollen stuck to its scales brushes onto stigma's flower. Some species of butterflies migrate over long distance; carry pollen to be shared across plants which are far apart from one another. This migration of pollens induces genetic variation in plants species and give a better chance at survival against different disease. These insects also provide food for other organisms, for example; birds, reptiles, amphibians and also acts as biological pest control. But the population of these insects decline rapidly due to human activities, habitat destruction, uses of pesticides and unawareness of people about the importance of flying flowers.

Keyword: *Butterflies, ecological indicators, pollinators, flying flower, nectar eater,*

INTRODUCTION

Butterflies are attractive addition to flower garden and more important insect than most people realize. As a wildlife indicator, butterflies tell us almost everything we need to know about the health of an ecosystem Dobson, 2012 [1]

Swengel demonstrated that in ecosystem, plant and animal species lives in sites with similar combinations of soil, topography, climate and geography. Some types of vegetation must be required for Butterfly species existence. Butterflies lives in particular place have particular habitat requirements. An interesting part of studying, localized butterflies is learning to find out the microhabitats they require. In ecosystem focus is on individual species pay attention to required microhabitats. In ecosystem natural events either favor or reduce butterfly population's characteristics of microhabitats occurring in that ecosystem [2].

Co-Evolution of Butterflies and Plants

In plant reproductive phenology, general flowering reported from West Malesia, it might be expected that there is co-evolution between plants and pollinators demonstrated by Asthonet [3]. Ehrlich demonstrates that butterflies herbivorous organisms' coevolved with plants [4].

Ehrlich and Raven [5] developed model for the co-evolution of plants and butterflies and summarized the host plant information for the butterflies. Feeny and Gilbert describe that Co-evolution involve adaptive radiation of plants that have evolved relative chemical protection from herbivores, followed by adaptive radiation on these plant groups of herbivores able to get around their defenses [6, 7].

Pollination

According to Webb, Pollination is the process in which pollens are transferred from male parts of flower to female parts of flower and reproduce sexually even over large areas. Nectar produces from flower containin nutritious vitamins, lipids, sugar, amino acid etc. which is important food source for pollinators. Butterflies are also pollinators and visit the flower to eat nectar; tiny scales on the butterfly bodies brush against anthers and pollen adhere to scales. Now the butterfly visit to another flower, the pollen which attach to its scales brush in to the stigma's flower. These insects are attractive and interesting [8].

Bekars demonstrates that nectar of many flowers, at which adult Lepidoptera feed, contains significant concentrations of a wide range of amino acids, which must contribute to its nutritional value [9]. American Heliconius butterflies enrich their nectar diet by collecting pollen grains, mixing them with nectar in the coils of the haustellum and ingesting the amino acids that diffuse from pollen grains, Gilbert [7] Amino acids ingested are of major significance in adult maintenance and reproductive capacity [10].

The butterfly proboscis adapted for reaching nectar at the base of long tubed flowers. Different species vary greatly in proboscis length. Butterflies are diurnal and some smaller skippers (Hesperiidae), are only capable of using shallow blossoms like Melaleucasieberi (Myrtaceae), in which the nectar is easily accessible [11]. Butterflies with longer proboscides can use the long, narrowly tubular blossoms of such genera as Pimelea (Thymelaeaceae) and Calytrix

(Myrtaceae), in which the nectar are deeply concealed the Calytrix flower type.

In Sarawak, Malaysia, (Momose) Butterfly pollinated flowers are tubular and brush like shapes. Butterfly pollinated flowers of family Leguminosae, Verbenaceae and Rubiaceae were odorless and orange in color when fresh, but they remained in inflorescence, turn reddish even after pollination and this phenomenon was common in tubular flowers like *Ixora* spp., Rubiaceae and brush flowers like *Bauhinia* spp. Leguminosae [12].

Genetic Variation in Plant Species

Kearney explains butterflies collect nectar from plant species, which induce genetic variation in the plants. Some butterfly species migrate over long distance and shared pollens across plants which are far away from one another. This helps plants to recover against disease and gives them a better chance at survival [13].

Ecological Indicators of Healthier Ecosystem

In many regions of the world Lepidoptera are accepted as the ecological indicators of the ecosystem health, Rosenberg et al., 1986; New et al., 1995; Beccaloni et al., 1995; Oostermeijer et al., 1998 [14, 15, 16, 17]. Butterflies have clear taxonomy their biology and life history are well defined [18, 19]. Physiological tolerances; habitat, temperature, light requirements have been quantified; Warren 1985, Thomas and Harrison 1992, [20, 21] and correlations with changes in ecosystem conditions have been determined by Bowman [22].

Ehrlich, 1984; Oostermeijer and van Swaay 1998 describes that Butterflies have high reproductive rates and are at low trophic level due to this response quickly to environmental stress. Many butterflies specialize on a specific plant species for oviposition or feeding [4, 16]. Butterflies tend to be easy to find and measure.

According to Dobson, 2012, in the last ten years 72% butterfly and moth species have declined. Butterflies react quickly to minor changes in the environment, providing an alarming signal for other reductions in wildlife and making them good indicator of biodiversity. So, they are best monitored group of insects in the world [1]. Some butterfly species are very sensitive to even light disturbance of natural forest. These species of butterflies are good indicators for natural forest; Kearney, 2015 [15].

Provide Food for Other Organisms

Butterflies provide food for number of animals such as birds, reptiles, amphibians etc. caterpillars provide an occasional meal for scorpions and ants. Eggs of some flies and wasps live as parasites inside caterpillar's body and feed on it. If populations of butterfly diminish, then population of birds, mice and other animals that rely on them as food source will also effect. This loss will collapse the entire ecosystem; Kearney, 2015 [13]. Stephen Dickie, explains: "Birds plan their whole breeding season around when caterpillars will be most abundant. If the butterfly and caterpillar numbers are depleted then there's not going to be a lot of food for developing chicks" Dobson, 2012 [1].

Predators

Some butterfly larvae feed on harmful insect for example Hoverfly larvae are mainly predators, often on aphids; Sommaggio, 1999 [22] so, caterpillars are also use as biological pest control.

A Flying Flower and Magic

Butterfly is a living flower, displaying its beauty wherever it goes. The bright colors of wings stand out against the blue sky and green foliage, attracting its mates. The bright colors prevent some potential predators by suggesting bad taste or poison. Before the start of winter, fragile Monarch butterfly migrates up to 2,000 miles, and form colonies in Mexico and part of California. When spring arrives they head north and east, laying eggs before they die. Though butterflies make the trip only once, they magically know where to go. Metamorphosis is magic in nature; a beautiful butterfly emerges fully formed from a chrysalis that was spun from a crawling caterpillar. The butterfly begins life as an egg that hatches into a larva or caterpillar which grows and pupa stage chrysalis; Kumar, 2013 [23].

Habitat Destruction

Human activities destroy the butterfly habitats. Global and climate fluctuate also effects the butterfly habitats. Governmental policy on forestry, farming and road planning has great effect on the abundance and distribution of butterflies; Hoskins, A. [27].

Pesticides

The distribution and abundance of butterflies decline due to the habitat destruction, Heath *et al.*, 1984 [24]. The use of pesticides on arable crops have profound harmful effects on farmland wildlife; Mellanby, 1981 [25] but its impact on butterflies is unknown. The use of insecticides has little evidence for the reduction in numbers; Heath [24]. The use of Herbicides with chemical fertilizers and drainage reduce the butterfly number indirectly by changing the unimproved grassland land in to improved pasture. Thomas explain that mostly butterfly rich farmland habitat is unimproved grassland. So, herbicides reduce the butterfly population [20].

In 1984 Rands and Sothorn examine the butterfly numbers on two plots of arable farmland in southern England. The field edge of one plot was unsprayed with herbicides, fungicides and insecticides from 1 January while other plot field was fully sprayed. Unsprayed and sprayed transect sections were paired up according to adjacent field boundary habitat type. On unsprayed plot 868 butterflies were recorded and 297 on the sprayed plot. In survey section 17 species of butterfly were recorded out of which 13 species of butterfly abundant on unsprayed field. Butterfly species less able to breed in sprayed field. So, use of herbicides on cereal crops reduces the butterfly number [26].

CONCLUSION AND RECOMMENDATIONS

The main conclusion of the study is that butterfly population is decline rapidly it is suggest that greater emphasis should be placed on management of habitat and better integration of protected areas.

Never capture a butterfly. If we remove a member of an already struggling species, we are contributing to the uphill battle they must fight for survival. Encourage people to leave butterflies alone to fly free. We must do more than admire their beauty. We must protect them. We should aware, the other peoples about the importance of butterflies and other insects. There should be introductory course about the protection and conservation of ecosystem and wildlife at school level.

A great way to help these insects survive is to eat organic foods, avoid herbicides in your personal landscaping, and to start cultivating milkweed and other nectar plants in your own garden. These insects need our help and we need their invaluable contributions to save entire ecosystems.
